

String distance

Given two strings str1 and str2, write a function to compute the Levenshtein distance between them. The Levenshtein distance is defined as the minimum number of single-character edits (insertions, deletions, or substitutions) required to change one string into the other.

Example 1: "kitten", "sitting" should return 3, as changing index 0 ('k' to 's'), 4 ('e' to 'i') and 6 (adding 'g') are enough to transform the strings.

Example 2: "flaw", "lawn" should return 2, as changing index 0 (dropping 'f') and 3 (adding 'n') is enough to transform the strings.

Input Format

str1 : a string str2 : a string

Constraints

(1 <= len(str1), len(str2) <= 1000)

Output Format

Return an integer, representing the Levenshtein distance between str1 and str2.

Sample Input 0

```
kitten sitting
```

Sample Output 0

```
3
```

Explanation 0

Minimum number of edits required: 3 Substituting 'k' with 's' - 1 Substituting 'e' with 'i' - 1 Inserting 'g' - 1

Sample Input 1

```
flaw lawn
```

Sample Output 1

```
2
```

Explanation 1

Minimum number of edits - 2 Removing 'f' - 1 Inserting 'n' - 1
